Abstract
A multi-resolution fusion algorithm, which combines aspects of region and pixel-based fusion. We use multi resolution decompositions to represent the input images at different scales, and introduce multi resolution or multi modal segmentation to partition the image domain at these scales. This segmentation is then used to guide the subsequent fusion process using wavelets. A region-based multi resolution approach allows us to consider low-level as well as intermediate- level structures, and to impose data-dependent consistency constraints based on spatial, inter- and intra-scale dependencies.

The wavelets used in image fusion can be classified into three categories Orthogonal, Bi-orthogonal and non-orthogonal. Although these wavelets share some common properties, each wavelet also has a unique image decompression and reconstruction characteristics that lead to different fusion results. In this project the above three classes are being compared for their fusion results. Normally, when a wavelet transformation alone is applied the results are not so good. However, if a wavelet transform and a traditional transform such as IHS transform or PCA transform are integrated for better fusion results may be achieved. Hence we introduce a new novel approach to improve the fusion method by integrating with IHS or PCA transforms.

The fusion results are compared graphically, visually and statistically and show that wavelet integrated methods can improve the fusion result, reduce the ringing or aliasing effects to some extent and make image smoother.

Keywords: Multi resolution, PCA Algorithm, panchromatic image

INTRODUCTION

Image fusion is a technique used to integrate a high-resolution panchromatic image with low-resolution multispectral image to produce a high-resolution multispectral image, which contains both the high-resolution spatial information of the panchromatic image and the colour information of the multispectral image. Although an increasing number of high-resolution images are available along with sensor technology development, image fusion is still a popular and important method to interpret the image data for obtaining a more suitable image for a variety of applications, such as visual interpretation and digital classification.

IMAGE FUSION CAN PROVIDE THE FOLLOWING FUNCTIONS

1. Sharpen the images
2. Improve geometric corrections
3. Substitute the missing information image with signals from another image
4. Replace defective data

ADVANTAGES

1) Improved system performance i.e detection recognition and resolution
2) Improved situation assessment
© WAVELET USED IN THE IMAGE FUSION

- BASIC WAVELET TRANSFORM THEORY

In wavelet transformation, the basis functions are set of dilated and translated scaling functions.

\[ \varphi_{j,k}(n) = 2^{j/2} \varphi(2^j n - k) \]

And a set of dilated and translated wavelet functions.

\[ \psi_{j,k}(n) = 2^{j/2} \psi(2^j n - k) \]

Where \( \varphi(n) \) and \( \psi(n) \) are the scaling functions and the mother wavelet functions respectively.

- DIFFERENT WAVELETS USED IN IMAGE FUSION

a. Orthogonal wavelet

The dilations and translation of the scaling function \( \varphi_{j,k}(x) \) constitute a basis for \( V_j \), and similarly \( \psi_{j,k}(x) \) for \( W_j \), if the \( \varphi_{j,k}(x) \) and \( \psi_{j,k}(x) \) are orthonormal, they include the following property.

\[ V_j \perp W_j \]

b. Bi-orthogonal wavelet

For Bi-orthogonal transform, perfect reconstruction is available. Orthogonal wavelets give orthogonal matrices and unitary transforms; bi-orthogonal wavelets give invertible matrices and perfect reconstruction. For bi-orthogonal wavelet filter, the Low pass and high pass filters do not the same length. The low pass and high pass filters do not have the same length. The low pass filter in

always. Symmetrical, while high pass filter could be either symmetric or anti – symmetric.

c. Non – orthogonal wavelet

A torus is a kind of non – orthogonal wavelet that is different from orthogonal and bi-orthogonal. It is a ‘stationary’ or redundant transform, i.e. decimation is not implemented during the process of wavelet transform, while the orthogonal or bi-orthogonal wavelet can be carried out using either decimation or un decimation mode.

Compared with other wavelet based fusion method, this method is relatively easy to implement. The limitation is that it uses a large amount of computer memory.

WAVELET BASED IMAGE FUSION METHOD

Additive wavelet based image fusion method

The whole process can be divided into four steps.

a) Histogram match
b) Wavelet decomposition
c) Details information combination
d) Inverse wavelet transforms
1) Apply the histogram match process between panchromatic image and different bands of the multispectral image respectively, and obtain three new panchromatic images PANR, PANG, PANB.

1) Use the wavelet transform to decompose new panchromatic images and different bands of multispectral image twice, respectively.

2) Add the detail images of the decomposed panchromatic images at different levels to the corresponding details of different bands in the multispectral image and obtain the new details component in the different bands of the multispectral image and obtain the new details component in the different bands of the multispectral image.

3) Perform the wavelet transform on the bands of multispectral images, respectively and obtain the fused image.

I. Integration of substitution method with wavelet method

In integration of substitution method divide two parts

a) Refers to substitution fusion method

b) Refers to the wavelet passed fusion method

The whole process consists of following steps

1) Transform the multispectral image into the IHS or PCA components.

2) Apply histogram match between panchromatic image and intensity component and obtain new panchromatic image.

3) Decompose the histogram matched panchromatic image and intensity component to wavelet planes respectively.

4) Replace the LL in the panchromatic decomposition with the LL of the intensity decomposition, add the detail images in the panchromatic decomposition to the corresponding detail image in the panchromatic decomposition to the corresponding detail images of the intensity and obtain LL , LH , HH and HL . Perform an inverse wavelet transform, and generate a new intensity. Transform the new intensity together with hue, saturation components or PC1, PC2, PC3 back into RGB space.

**ALGORITHM FOR PCA**

1. Representation of training images

   Obtain face images A1,A2,…,AM for training. Every image must of the same size(NxN).

2. Computation of the mean image

   The images must be mean centered. The pixel intensities of the mean face image is obtained by adding the corresponding pixels from each image. The mean image can be computed as

   \[
   m = \frac{1}{M} \sum_{c=1}^{M} A_c
   \]

3. Normalization Process of Each Image in the Database

   Subtract the mean image from the training images.

   \[
   \tilde{A}_c = A_c - m \quad \text{where, } c=1 \text{ to } M
   \]
4. Calculation of Covariance Matrix

The covariance matrix, which is of the order of N×N, is calculated as given by

\[ C = \frac{1}{M} \sum_{c=1}^{M} (A-m)^T(A-m) \]

5. Calculation of Eigen values and Eigen vectors

Find the Eigen values of the covariance matrix C by solving the equation \((C-\lambda I)=0\) to calculate the Eigen values \(\lambda_1, \lambda_2, \ldots, \lambda_N\).

For specific Eigen value \(\lambda_1\) solve the system of N equations

\((C-\lambda I)=0\)

To find the Eigen vector X Repeat the procedure for N Eigen values to find \(X_1 \ldots X_n\) Eigen vectors. The relation between Eigen vectors and Eigen value is given as \(X_i^T(AA^T)X_i=\lambda_i\). Where \(X_i\) indicates the Eigen vectors and \(\lambda_i\) indicates corresponding Eigen values.

6. Sorting the Eigen values and Eigen vectors

The Eigen vectors are sorted according to corresponding Eigen values in descending order. The Eigen vector associated with the largest Eigen value is one that reflects the largest variance in the image.

7. Choosing the best ‘k’ Eigen Vectors

Keep only ‘k’ eigenvectors corresponding to the ‘k’ largest eigen values. Each face in the training set can be represented as a linear combination of the best ‘k’ eigenvectors.

EXPERIMENTAL RESULTS

Five kinds of wavelet based fusion methods and two kinds of wavelet based integration method are implemented to test and compare their fusion results. All the fusion results are analyzed statistically by using correlation coefficients. The higher the value of the correlation coefficients, the more similar the fused image is to the corresponding original multispectral image.

APPLICATIONS

- Medical image Application
- Satellite Application

CONCLUSION

Compare wavelet based and wavelets integrated fusion methods. Wavelet based fusion extracts spatial details from high resolution bands. In this manner the colour distortion can be reduced to a certain extent, but the fused image appears similar to a high pass filtered image, e.g. the colour appears not to be smoothly integrated into the spatial features. The wavelet integrated method can improve the fusion result, reduce the ringing or aliasing effects to some extent and make the whole image smoother.

FUTURE SCOPE

Wavelet based image fusion is further implemented to the following aspects

- Fusion of radar and optical data
- Development of one method to evaluate the partial and spectral Quality of a fused image.

ACKNOWLEDGMENT

The authors would like to express their cordial thanks to their esteemed patrons Mr. B. Abdul Raheem, Head of Electronics and Communication Department, AITS, Rajampet, and also to our beloved Asst professors, A. Soma Sekhar and B. Sreenivasa Rao.
